## \* Function in Python:

Functions are reusable block of Code

### → Types of Functions:

a.) Pre-defined functions → Print(), Sum(), input(), append()

b.) User-defined functions →

1.) Step-1 - Using def keyword.

2.) Step-2 - Name of function.

3.) Step-3 - Logic or body of function

4.) Step-4 - Call the function (Name of function).

### → Syntax:

```
def function name():
```

```
    logic
```

```
name-function() - calling.
```

1.) Function to add two numbers?

def add(): — Function declaration

```
a = 10
b = 5
c = a + b
print(f"Sum is: {c}")
```

Logic Code block

add() — Calling the function

2.) Function to add square of a number till given value.

~~i = 1~~  
def my\_squ():

i = 1

n = 3

Sum = 0

while (i <= n):

Sum += i \*\* 2

i += 1

print(f"Total Square Value is: {Sum}")

my\_squ()

3.) ~~n = 1234~~ Function to add digits.

```
def digit-add():
```

```
    n = 1234
```

```
    sum = 0
```

```
    while (n > 0):
```

```
        digit = n % 10
```

```
        sum += digit
```

```
        n //= 10
```

```
    print(f"total sum is: {sum}")
```

```
digit-add()
```

\* Arguments and Parameters :-

i-) Parameters :

These are values which we pass when we create a function.

ii-) Arguments :

These are values which we pass when we call a function.

Q-1.) Program / Function of Addition.

```
def my_add(a, b): # (a, b) are parameters
```

```
    c = a + b
```

```
    print("Sum is: " + c)
```

```
my_add(12, 10) # (12, 10) are arguments
```

0.2.) Function to check even or odd?

```
def even_or_odd(a):
```

```
    a = int(input("Enter a Number: "))
```

```
    if (a % 2 == 0):
```

```
        print("Even Number")
```

```
    else:
```

```
        print("Odd Number")
```

```
even_or_odd()
```

\*

# Lambda function :-

- A Lambda function can take any number of arguments but can have only one expression.

## Syntax :

lambda arguments : expression

1.)

Ex-1 :

```
x = lambda a : a + 5
```

```
print(f"total is : {a(8)}")
```

2.)

```
x = lambda a, b : a * b
```

```
print(f"total is : {a(5, 3)}")
```

3.)

```
x = lambda a, b, c : a + b + c
```

```
print(f"Sum is : {x(3, 3, 4)}")
```

## \* Arguments in functions :-

### i.) \*args (Non-Keyword Arguments) :-

\*args allows us to pass multiple arguments to a function. It collects them into a tuple.

```
def add_numbers(*args):
```

```
    total = sum(args)
```

```
    print("Sum is:", total)
```

```
add_numbers(5, 10, 15)
```

### ii.) \*\*kwargs (Keyword Arguments) :-

\*\*kwargs allow us to pass multiple keyword arguments (name-value pairs).

- It collects them to a dictionary.

```
def print_details(**kwargs):
```

```
    for key, value in kwargs.items():
```

```
        print(f"{key}: {value}")
```

```
print_details(name="Amaan", age=22)
```

Q.iii) Using \*args and \*\*kwargs together:

- we can use both in the same function but args must come before \*kwargs.

```
def display_info(*args, **kwargs):
```

```
    print("Positional arguments:", args)
```

```
    print("keyword arguments:", kwargs)
```

```
display_info(1, 2, 3, name="Saurabh", age=25)
```

#### iv.) Required arguments :-

- These are arguments that must be passed to a function otherwise, Python throws an error, There is no default value for these arguments.

```
def greet(name):
```

```
    print("Hello", & name)
```

```
greet("Amaan")
```

#### v.) Default arguments : (Optional)

- These arguments have a default value assigned. If no value is provided, Python uses the default.

```
def greet(name = "Guest"):
```

```
    print(f"Hello & name!")
```

```
greet()
```

3.)

vi.)

Return keyword:

The Return keyword sends a value back from a function. if returns is not used

#

Questions:-

1.)

Find the maximum number using \*args:-

```
def find_max(*args):
```

```
    return max(args)
```

```
print(find_max(2, 100, 3, 10))
```

Output - 100

2.)

Calculate product of numbers using \*args

```
def product(*args):
```

```
    result = 1
```

```
for i in args:
```

```
    result *= i
```

```
return result
```

```
print(product(2, 3, 4))
```

output - 24

3.) Generate a full name using \*\*kwargs:-

```
def full_name(**kwargs):
```

```
    F"return return (kwargs.get('first-name', 'unknown'))
```

```
        {kwargs.get('last-name', 'Mehta')}"
```

4.) Count vowels in a Given String using return:

```
def Count_Vowel (String):
```

```
    Vowels = 'aeiou AEOU'
```

```
    return sum(1 for char in String in vowels)
```

5.) Create a Shopping Cart using args and \*kwargs

```
def Shopping_Cart(*items, **prices):
```

```
    total = Sum(prices[item] for item in  
                items if item in prices)
```

```
    return total
```

```
print(Shopping_Cart("apple", "Mango", apple=30,  
                   *Mango=20))
```
